Refractory anaphylaxis

No improvement in respiratory or cardiovascular symptoms despite 2 appropriate doses of intramuscular adrenaline

Establish dedicated peripheral IV or IO access

Give rapid IV fluid bolus e.g. 0.9% sodium chloride

Give IM* adrenaline every 5 minutes until adrenaline infusion has been started

*IV boluses of adrenaline are not recommended, but may be appropriate in some specialist settings (e.g. peri-operative) while an infusion is set up

Give high flow oxygen

Titrated to SpO₂ 94–98%

Monitor HR, BP, pulse oximetry and ECG for cardiac arrhythmia

Take blood sample for mast cell tryptase

Seek expert¹ help early

Critical care support is essential

Start adrenaline infusion

Adrenaline is essential for treating all aspects of anaphylaxis

Follow local protocol

Peripheral low-dose IV adrenaline infusion:
- 1 mg (1 mL of 1 mg/mL [1:1000]) adrenaline in 100 mL of 0.9% sodium chloride
- Prime and connect with an infusion pump via a dedicated line
- DO NOT ‘piggy back’ on to another infusion line
- DO NOT infuse on the same side as a BP cuff as this will interfere with the infusion and risk extravasation
  - In both adults and children, start at 0.5–1.0 mL/kg/hour, and titrate according to clinical response
  - Continuous monitoring and observation is mandatory
  - ↑↑ BP is likely to indicate adrenaline overdose

Continue adrenaline infusion and treat ABC symptoms

Titrated according to clinical response

IF REFRACTORY TO ADRENALINE INFUSION

Consider adding a second vasopressor in addition to adrenaline infusion:
- Noradrenaline, vasopressin or metaraminol
- In patients on beta-blockers, consider glucagon

Consider extracorporeal life support

Cardiac arrest – follow ALS ALGORITHM
- Start chest compressions early
- Use IV or IO adrenaline bolus (cardiac arrest protocol)
- Aggressive fluid resuscitation
- Consider prolonged resuscitation/extracorporeal CPR

= Airway

Partial upper airway obstruction/stridor:
Nebulised adrenaline (5mL of 1mg/mL)

Total upper airway obstruction:
Expert help needed, follow difficult airway algorithm

= Breathing

Oxygenation is more important than intubation

If apnoeic:
- Bag mask ventilation
- Consider tracheal intubation

Severe/persistent bronchospasm:
- Nebulised salbutamol and ipratropium with oxygen
- Consider IV bolus and/or infusion of salbutamol or aminophylline
- Inhalational anaesthesia

= Circulation

Give further fluid boluses and titrate to response:
Child 10 mL/kg per bolus
Adult 500–1000 mL per bolus
- Use glucose-free crystalloid (e.g. Hartmann’s Solution, Plasma-Lyte®)
- Large volumes may be required (e.g. 3–5 L in adults)

Place arterial cannula for continuous BP monitoring
Establish central venous access

IF REFRACTORY TO ADRENALINE INFUSION

Consider adding a second vasopressor in addition to adrenaline infusion:
- Noradrenaline, vasopressin or metaraminol
- In patients on beta-blockers, consider glucagon

¹Intravenous adrenaline for anaphylaxis to be given only by experienced specialists in an appropriate setting.
